+ question
full model
answer $a_0(q)$
4 harmless passes:
frames shifted by ½ or ¼
of an interval; options
cycled or reversed
compressed pass m
(method, budget)
answer $a_m(q)$
for each held-out pass k:
S_k = questions on which the
other three passes agree
with a_0
flip rates on S_k:
$F_m(S_k)$ and $F_{n_k}(S_k)$
$\Delta_m = \frac{1}{4}\sum_k [\, F_m(S_k) - F_{n_k}(S_k) \,]$
excess flips beyond noise
95% interval of Δ_m
(videos resampled, 2000 draws)
lossy: lower bound > 0
noise-equivalent: upper bound < δ
inconclusive: neither
